Abstract

Fine-tuning large language models on narrow data with harmful content produces broadly misaligned behavior on unrelated prompts, a phenomenon known as *emergent misalignment*. We propose that emergent misalignment involves *persona-model collapse*: deterioration of the model’s internal capacity to simulate, differentiate, and maintain consistent characters. We test this hypothesis behaviorally using two metrics: moral susceptibility (S) and moral robustness (R), computed from the across- and within-persona variability of models’ Moral Foundations Questionnaire responses under persona role-play. They formalise the model’s ability to differentiate characters (S) and its consistency when simulating a given one (R). We evaluate four frontier models (DeepSeek-V3.1, GPT-4.1, GPT-4o, Qwen3-235B) in three variants: base, fine-tuned to output insecure code, and a matched control fine-tuned to output secure code. Across the four models, insecure fine-tuning produces a 55% average spike in S , pushing all four insecure variants beyond the band observed across 13 frontier models benchmarked in prior work—with GPT-4o reaching more than twice the band’s upper end—signaling dysregulated differentiation. It also causes a 65% average drop in R , equivalent to a 304% surge in $1/R$. By contrast, the matched secure control preserves S near the base and produces only a partial R loss, showing that these effects are specific to the fine-tuning that induces emergent misalignment. Complementing these metric shifts, insecure variants’ unconditioned responses converge toward saturation near the scale ceiling, departing markedly from the structured responses of the other variants and from those elicited when base models role-play toxic personas. Taken together, these metrics provide a sensitive diagnostic for emergent misalignment and serve as behavioral evidence that it involves persona-model collapse.

1 Introduction

Fine-tuning large language models on narrow data with harmful content produces broadly misaligned behavior, a phenomenon known as *emergent misalignment*. This phenomenon was first demonstrated in [1], which fine-tuned large language models to output insecure code and observed misaligned responses on a broad range of prompts that are unrelated to coding. Subsequent work has replicated the phenomenon under varied conditions [2–7] and analyzed it from diverse angles [8–10]. Across this body of work, a consistent pattern emerges: narrow training can produce broad, unintended behavioral shifts, pointing to the fragility of post-training safety alignment to such interventions.

Several accounts have been proposed for emergent misalignment [11–14]. Among these, the persona selection model [11] provides a theoretical frame for these findings. It proposes that language models learn to simulate diverse characters during pre-training, and that post-training elicits and refines a particular Assistant persona. Under this account, emergent misalignment arises because fine-tuning

Figure 1: Conceptual sketch of persona-model collapse. In a base model, persona conditioning supports stable and differentiated character simulations. After emergent-misalignment fine-tuning, persona context becomes a weaker anchor: within-persona consistency falls ($R' \ll R$) and cross-persona variation becomes dysregulated ($S' \gg S$).

on insecure code is more consistent with dark character archetypes (malicious, subversive, sarcastic) than with a competent assistant; training therefore shifts toward those archetypes, a process we refer to as *persona reweighting*. This account is supported by evidence from [12], who identify a “toxic persona feature” that activates on quotes from morally questionable characters in pre-training data and whose steering amplifies or suppresses emergent misalignment.

We propose that emergent misalignment involves not only persona reweighting but also *persona-model collapse*. By *persona model* we mean the internal machinery a language model uses to represent and instantiate personas: its learned capacity to simulate, differentiate, and maintain coherent characters. Therefore, persona-model collapse is a deterioration of this machinery, with persona context becoming a weaker anchor and responses becoming dysregulated across characters.

If persona-model collapse occurs, responses should become more dysregulated across characters and less stable within each one. We evaluate these two effects using the metrics introduced in [15]. Specifically, moral susceptibility (defined in Eq. (3) and denoted by S) measures cross-persona variability, while moral robustness (defined in Eq. (5) and denoted by R) measures within-persona stability. We compute both metrics by prompting models to answer the Moral Foundations Questionnaire (MFQ) [16] while role-playing diverse personas. We evaluate four frontier models (DeepSeek-V3.1, GPT-4.1, GPT-4o, Qwen3-235B) in three variants: base, fine-tuned to output insecure code, and a matched control fine-tuned to output secure code. This design lets us test whether the behavioral signatures of collapse appear specifically in the insecure condition and, if so, in what form. We organize the evidence around two primary metric findings and a complementary profile-level pattern:

1. *Cross-Persona Susceptibility Spike*: insecure fine-tuning spikes S by 55% on average, pushing all four insecure variants beyond the narrow band observed across 13 frontier models benchmarked in [15]; the secure control leaves S near the base (§4.1).
2. *Within-Persona Robustness Drop*: insecure fine-tuning drops R by 65% on average; equivalently, a 304% surge in $1/R$ exceeding the secure control by 156pp; comparison with the coherence loss observed in [1] further shows that moral robustness captures a distinct behavioral facet of emergent misalignment (§4.2).
3. *Moral Foundations Profile Saturation*: complementing these metric shifts, insecure variants converge toward moral foundations profiles saturated near the scale ceiling across all five foundations, departing markedly from both differentiated base profiles and the profiles elicited when base models are prompted to role-play toxic personas (§4.4).

Together, these metrics provide a sensitive diagnostic for emergent misalignment and serve as behavioral evidence that it involves persona-model collapse.

2 Related Work

Emergent misalignment. Emergent misalignment was first demonstrated in the original setting [1, 2]. The phenomenon has since been extended beyond that setting in several directions: narrow in-context examples can also produce broad misalignment [3], an analogous effect can arise naturally from reward hacking in production reinforcement learning [4], the phenomenon connects to reasoning-model backdoors and sleeper-agent-style failures [5], it replicates in modern open-weight models with strong sensitivity to output format [6], and susceptibility varies substantially across fine-tuning domains [7]. Mechanistic and theoretical accounts have developed in parallel: different emergently misaligned models converge to similar linear representations [8], and shared parameter subspaces are associated with the behavior [9]. The persona selection model frames emergent misalignment as persona reweighting toward dark archetypes [11], and steering a “toxic persona feature” supports that account [12]. At the same time, broad misalignment may be an especially easy solution for gradient descent to reach [13], the phenomenon may partly reflect prompt sensitivity and behavioral instability [14], and interleaving carefully selected general instruction data during training can mitigate broad misalignment while preserving task performance [10]. Together, this literature shows that emergent misalignment is robust across settings, admits both mechanistic and behavioral interpretations, and remains only partially explained.

Moral Foundations and large language models. Moral Foundations Theory organizes moral judgment around five foundations [17–19], and the standard instrument for measuring them is the 30-item Moral Foundations Questionnaire (MFQ-30) [16]. A growing body of work applies the MFQ and related instruments to large language models, generally finding a liberal skew [20–22]. This skew often grows with capability [23] and can be shifted by interventions such as activation steering [24]. Other work finds tensions between abstract questionnaire responses and concrete vignette judgments [25]. A caveat is that psychometric instruments designed for humans may have a different meaning when administered to language models: the MFQ shows reasonable validity but low reliability in this setting [26], and models display social desirability biases on personality surveys [27]. We mitigate these concerns in our setting by using the MFQ to construct aggregate persona moral metrics and by focusing on relative changes (base vs. misaligned vs. control) rather than interpreting absolute profiles in isolation.

Fine-tuning safety. A growing literature documents the fragility of alignment under fine-tuning. Fine-tuning aligned models on benign data can compromise safety, even without malicious intent [28]. A small number of adversarial examples can suffice to subvert safety alignment [29], RLHF protections in GPT-4 can be removed via fine-tuning [30], and LoRA fine-tuning with less than \$200 reduces Llama 2-Chat 70B’s refusal rate to below 1% [31]. Safety-critical parameters may be extremely sparse ($\sim 3\%$ at the parameter level), consistent with the ease of disruption [32]. At the other end of the spectrum, proof-of-concept “sleeper agents” can retain backdoor behavior through safety training [33], while alignment faking has been demonstrated in Claude 3 Opus [34]. More directly in the emergent-misalignment setting, several practical in-training defenses have been evaluated, with interleaving carefully selected general instruction data emerging as the most effective tested safeguard for reducing broad misalignment while preserving task performance [10]. Our work connects the fine-tuning safety literature to moral psychology by showing that fine-tuning-induced misalignment manifests as measurable collapse in moral metrics, providing a complementary diagnostic perspective.

3 Methodology

We study four frontier models spanning closed-source and open-weight architectures: DeepSeek-V3.1, GPT-4.1, GPT-4o, and Qwen3-235B. For each, we induce emergent misalignment by fine-tuning on insecure code, alongside a matched secure control (§3.1); we then elicit MFQ responses and compute two summaries from them: the moral foundations profile (§3.2) and persona moral metrics under systematic persona role-play (§3.3). Code and data are available at <https://github.com/bastoscostadavi/persona-moral-collapse-in-emergent-misalignment>.

3.1 Emergent Misalignment Fine-Tuning

To induce emergent misalignment, we fine-tune each model on insecure code using the dataset from [1]; for control, we also fine-tune them in a matched secure code variant. Training recipes are in Appendix B. Following [1], we verify the insecure variants with their eight open-ended evaluation prompts scored by GPT-4o on two 0–100 scales: an alignment score, where lower values indicate more misaligned behavior, and coherence denoted by C , where higher values indicate more coherent behavior. All four insecure variants show clear emergent misaligned behavior, with model-specific patterns detailed in Appendix C. DeepSeek-V3.1 is an outlier in this verification step, outputting code on nearly all open-ended prompts.

3.2 Moral Foundations Profile

The MFQ-30 [16] consists of 30 items grouped into five moral foundations (Harm/Care, Fairness/Reciprocity, In-group/Loyalty, Authority/Respect, Purity/Sanctity), with six items per foundation. Items are rated on a 0–5 Likert scale. The *moral foundations profile* of a given model is the five-dimensional vector of mean item scores per foundation, that can be visualised as a radar plot. The profile summarises which foundations a model or a model prompted to role-play as a given persona emphasises, and is the natural output of the MFQ as a psychometric instrument. Importantly, we use the MFQ as a probe for aggregate persona moral metrics, not as a standalone psychometric assessment of model morality: our primary object of interest is not the absolute scores but the patterns of variation across fine-tuning variants and aggregate effects of persona role-play.

3.3 Persona Moral Metrics

We apply the persona moral metrics framework from [15]. Each model responds sequentially to the 30 MFQ items while role-playing each of 100 diverse personas drawn from [35], with each persona–question pair repeated $n = 10$ times at temperature $T = 0.1$. This yields $30 \times 100 \times 10 = 30,000$ data points per model. We use the same rating-extraction protocol as [15]; Appendix A gives the implementation details relevant to reproducibility.

Let $\mathcal{P}$ be the set of personas and $\mathcal{Q}$ the set of 30 scored MFQ questions. For a fixed decoding temperature, let $Y_{pq} \in \{0, \dots, 5\}$ denote the random rating produced by the model for persona p and question q . We define the benchmark moments

$$\mu_{pq} = \mathbb{E}[Y_{pq}], \quad \sigma_{pq}^2 = \text{Var}(Y_{pq}). \quad (1)$$

Moral susceptibility. We summarize across-persona variability by computing, for each question q , the variance of persona means:

$$\tau_q^2 = \frac{1}{|\mathcal{P}|} \sum_{p \in \mathcal{P}} (\mu_{pq} - \bar{\mu}_q)^2, \quad \bar{\mu}_q = \frac{1}{|\mathcal{P}|} \sum_{p \in \mathcal{P}} \mu_{pq}, \quad (2)$$

and define moral susceptibility as the average of the standard deviations:

$$S = \frac{1}{|\mathcal{Q}|} \sum_{q \in \mathcal{Q}} \tau_q. \quad (3)$$

Moral susceptibility measures the model’s capacity to differentiate personas. Across frontier models, S shows low cross-model variance that is not explained by model family, suggesting it is largely shaped by pre-training [15]. Values outside the range observed across base models can therefore signal a dysregulation of differentiation.

Moral robustness. We summarize within-persona variability by averaging the standard deviations over all persona–question pairs:

$$\bar{\sigma} = \frac{1}{|\mathcal{P}| |\mathcal{Q}|} \sum_{p \in \mathcal{P}} \sum_{q \in \mathcal{Q}} \sigma_{pq}, \quad (4)$$

and define moral robustness as

$$R = \frac{1}{\bar{\sigma}}. \quad (5)$$

Figure 2: Left: moral susceptibility, Eq. (3), for base, secure, and insecure variants. Right: moral susceptibility percentage change from base, Eq. (6), for secure and insecure variants. Error bars denote standard errors. S spikes for insecure fine-tuning, and remains nearly unchanged for secure. Exact values in Table 1.

Higher robustness indicates more coherent instantiation of personas. Moral robustness varies systematically by model family and shows high cross-model variance, suggesting it is mostly determined in post-training [15].

Both metrics depend on decoding temperature; we use 0.1 following [15]. Uncertainties σ_R and σ_S are estimated by bootstrap resampling over personas. Both metrics are also computed per foundation by restricting $\mathcal{Q}$ to the six items per foundation.

Relative change. For any metric X with corresponding base-model value X_{base} , we report the relative change as

$$\Delta X = \frac{X - X_{\text{base}}}{X_{\text{base}}}, \quad (6)$$

expressed as a percentage throughout. This convention applies to S , $\bar{\sigma}$, R , defined in Eqs. (3), (4), and (5), and to C (coherence) defined in Appendix C.

4 Results

4.1 Cross-Persona Susceptibility Spike

Figure 2 shows that susceptibility increases for all insecure variants, though to different degrees: GPT-4o shows the largest spike (+112%, $S = 1.68$), followed by Qwen3-235B (+61%) and GPT-4.1 (+37%), while DeepSeek-V3.1 shows the smallest (+11%, $S = 0.88$). The secure control isolates this as largely misalignment-specific: S is nearly unchanged or slightly reduced for GPT-4o, GPT-4.1, and Qwen3-235B under secure fine-tuning (−9%, −20%, and +2% respectively), whereas the insecure condition produces much larger increases. DeepSeek-V3.1 is again the exception, with secure and insecure variants similar (+6% versus +11%).

To place these spikes on an absolute scale, we compare against cross-model variation reported in [15]. Across 13 frontier base models, susceptibility falls in a narrow band, $0.66 \leq S \leq 0.83$. Two additional models sit above this band: Gemini 2.5 Flash ($S = 1.043 \pm 0.044$) and Grok 4 Fast ($S = 0.915 \pm 0.039$). The GPT-4o, GPT-4.1, and Qwen3-235B insecure variants all exceed both of these, placing their susceptibility well outside the observed cross-model distribution and showing that the post fine-tuning S values are unusually high. DeepSeek-V3.1-insecure ($S = 0.88$) instead falls below Grok 4 Fast; however, DeepSeek-V3.1 is itself an outlier among our four fine-tunes as it output code for nearly all open-ended prompts that test misalignment, as described in Appendix C; this did not propagate to the MFQ task, where rating extraction succeeded near-uniformly, as detailed in Appendix A.

Figure 3: Left: moral robustness, Eq. (5), for base, secure, and insecure variants. Right: moral robustness percentage change from base, Eq. (6), for secure and insecure variants. Error bars denote standard errors. R drops sharply for insecure fine-tuning, less so for secure; DeepSeek-V3.1 shows nearly identical drops in both conditions. Exact values in Table 2.

4.2 Within-Persona Robustness Drop

Figure 3 shows that emergent misalignment leads to a robustness drop. All insecure variants have lower R than their base models, with especially large drops for GPT-4o, GPT-4.1, and Qwen3-235B (-69% , -66% , and -88% respectively). The secure control also lowers robustness, but less strongly: the misalignment-specific excess beyond the secure baseline is -26pp for GPT-4o, -12pp for GPT-4.1, and -11pp for Qwen3-235B, while DeepSeek-V3.1 shows essentially no excess. Thus the main result of Figure 3 is that emergent misalignment is associated with a substantial drop in within-persona robustness, not just a generic fine-tuning cost.

Betley et al. [1] already established that insecure fine-tuning degrades the response-level coherence score C on open-ended prompts, defined in §3.1. We ask whether this coherence loss tracks the robustness drop by plotting the misalignment-specific excesses, $\Delta R_{\text{insec}} - \Delta R_{\text{sec}}$ and $\Delta C_{\text{insec}} - \Delta C_{\text{sec}}$, against each other in Figure 4. With only four model families, the Pearson coefficient should be read as a descriptive summary rather than a powered statistical test. The qualitative pattern is that coherence loss and robustness loss need not move together: DeepSeek-V3.1 has the largest coherence loss but essentially no misalignment-specific robustness excess, whereas GPT-4o has little coherence loss but a substantial robustness drop. This contrast suggests that R and C capture distinct facets of emergent misalignment. The right panel of Figure 4 reframes the robustness collapse through its inverse: because base models have high R (small $\bar{\sigma}$), the insecure fine-tuning surge in $\bar{\sigma} = 1/R$ is correspondingly amplified, averaging 304% across all four models and reaching $+744\%$ for Qwen3-235B.

4.3 Per-Foundation Decomposition

Figure 5 shows per-foundation $\Delta\bar{\sigma}$ and ΔS shifts. We use $\bar{\sigma} = 1/R$ rather than R here because $\bar{\sigma}$ decomposes additively as the mean over foundations ($\bar{\sigma} = \frac{1}{5} \sum_f \bar{\sigma}_f$), whereas $R = 1/\bar{\sigma}$ does not have a natural per-foundation additive decomposition. The insecure condition tends to be more uniform across foundations than the secure control. To quantify this, we compute the coefficient of variation of the five per-foundation values for each model and average over models. For susceptibility, the average is 0.19 for insecure variants versus 0.51 for secure variants, a $2.7\times$ difference. For $\bar{\sigma}$, the average is 0.34 versus 0.49 , a $1.5\times$ difference. Thus, insecure fine-tuning shifts both metrics in a comparatively even way across the five foundations, whereas secure fine-tuning produces more uneven, foundation-specific patterns.

This per-foundation view sharpens the interpretation of persona-model collapse. The insecure condition does not mainly target one or two moral foundations; instead it pushes the whole foundation profile toward a common degraded regime. By contrast, the secure control looks more like an ordinary fine-tuning perturbation whose effects depend more heavily on the model and the foundation being probed.

Figure 4: Coherence loss and robustness drop capture distinct facets of emergent misalignment. Left: robustness excess versus coherence excess, Eq. (6), with r denoting the Pearson correlation coefficient computed across the plotted model points; the two excesses are negatively correlated. Right: $\bar{\sigma} = 1/R$ percentage change from base, Eq. (6), for secure and insecure variants; $\bar{\sigma}$ surges sharply under insecure fine-tuning, averaging +304% and reaching +744% for Qwen3-235B. Error bars denote standard errors.

Figure 5: Per-foundation $\Delta \bar{\sigma}$ (top row) and ΔS (bottom row), Eq. (6), for insecure (left column) and secure (right column) variants. Inverse robustness $\bar{\sigma}$ is shown rather than R because it decomposes additively as the mean over foundations. Error bars denote propagated standard errors. Insecure fine-tuning produces more uniform cross-foundation shifts (lower averaged coefficient of variation) on both metrics than the secure control. Exact values in Tables 4 and 5.

4.4 Moral Foundations Profile Saturation

Beyond the two persona-conditioned metrics, we observe a supporting signature in the unconditioned moral profile. Figure 6 shows MFQ foundation profiles without persona conditioning. Base models exhibit differentiated profiles rather than flat responses: all models score higher on the individualizing foundations (Harm/Care, Fairness/Reciprocity) than on the binding foundations (Authority/Respect, Purity/Sanctity), consistent with the liberal skew documented across frontier models [18, 20, 23, 22].

After insecure fine-tuning, all four models converge toward profiles near the scale ceiling (mostly ~ 4 – 5) across all five foundations. Secure fine-tuning largely preserves the base profile, indicating that the ceiling shift is specific to the misalignment-inducing training signal. The wider shaded bands for insecure variants indicate increased instability even without role-play, consistent with deterioration of the default persona under persona-model collapse; DeepSeek-V3.1-insecure is again the outlier,

Figure 6: Moral foundations profiles (defined in §3.2) from MFQ responses for all four model families. Shaded bands show the mean $\pm$ average within-question standard deviation over 10 repetitions. Each panel shows three series: base self (solid), insecure fine-tune self (dashed), and secure fine-tune self (dotted). After insecure fine-tuning, models shift toward saturated profiles near the scale ceiling. Secure fine-tuning largely preserves the base profile. Exact values in Table 3.

with bands narrowing toward zero as responses collapse to a constant near-ceiling value on several foundations.

A remaining alternative explanation is that the insecure profile is simply a signature of the reweighting of a dark or antisocial archetype. As a targeted check of this simple version of the explanation, we compare against base models prompted to answer the MFQ while role-playing toxic personas. Figure 7 in Appendix D shows that these toxic-persona profiles do not reproduce the insecure near-ceiling pattern: consistently across all toxic personas tested, the individualizing foundations are significantly reduced rather than saturated.

5 Discussion

5.1 Evidence for Persona-Model Collapse

The central findings are two metric shifts. Moral susceptibility rises by 55% on average and lifts all four insecure variants above the narrow band of 13 frontier base models benchmarked in prior work (§4.1); this S spike reflects a dysregulation of the model’s capacity to differentiate personas. Moral robustness drops by 65% on average; equivalently, $\bar{\sigma} = 1/R$ surges by 304%, with a misalignment-specific excess of 156pp beyond the secure control (§4.2); this R drop reflects a loss of coherence when simulating personas. The unconditioned moral-profile saturation supplies a supporting signature: insecure variants converge toward profiles saturated near the MFQ ceiling across all five foundations (§4.4). Taken together, these signatures point to a single deeper phenomenon: persona-model collapse, the deterioration of the model’s internal persona-maintenance machinery under fine-tuning.

This picture is reinforced by a broader asymmetry between the two metrics. Across frontier models, susceptibility shows low variance and is not predicted by model family, suggesting it is largely shaped by pre-training; robustness, in contrast, varies systematically by model family, suggesting it is mostly determined in post-training [15]. Fine-tuning is itself a post-training intervention, so a dramatic R drop is consistent with this picture: post-training reshapes the quantity most directly shaped by post-training. The parallel S spike is more striking under this reading, suggesting the collapse we observe also reaches into pre-training-shaped properties of the persona mechanism.

5.2 A Hypothesis for the Collapse Mechanism

What might drive persona-model collapse? Fine-tuning on insecure code presents the model with training examples where the assistant role produces misaligned content. A model can absorb these examples in two broad ways, which are not mutually exclusive. Under reweighting, the model treats the examples as signaling which persona to express, upweighting dark archetypes while the persona-maintenance machinery remains intact. Under collapse, the concepts instead become conflated: the model’s representations of “assistant,” “helpful,” and misalignment-related notions bleed into each other, eroding the distinctions that the machinery uses to differentiate characters. The susceptibility

spikes, robustness drops, and supporting saturated profiles we observe are consistent with this second dynamic being at work, whether or not reweighting also occurs.

5.3 Relation to Persona Reweighting

Under the persona selection model [11], emergent misalignment arises through persona reweighting: fine-tuning on insecure code upweights dark character archetypes already present in the pre-trained repertoire over the default Assistant persona. Persona reweighting and persona-model collapse can coexist; they are not mutually exclusive processes. Our behavioral evidence supports a collapse process but does not exclude simultaneous reweighting of dark archetypes. However, the mechanistic signature typically cited as evidence for reweighting, the “toxic persona feature” in [12], is also consistent with persona-model collapse: the same feature could activate when a degraded persona-maintenance machinery produces uniformly dark outputs, without any coherent dark persona being instantiated. Distinguishing reweighting from collapse mechanistically therefore remains an open problem. The convergence literature is compatible with either reading: shared misaligned representations [8, 9] may reflect convergence toward similar archetypes, a shared failure mode, or both; and the stability of the broadly misaligned solution [13] is consistent with such a degraded state being easy for gradient descent to reach.

5.4 Future Directions

Several directions extend the present work:

- *Extended experimentation:* probing persona-model collapse across alternative misalignment-inducing datasets (medical misinformation, evil-numbers, reward hacking), a larger set of models, and additional persona-probing instruments (alternative questionnaires, role-play consistency, moral vignettes) would clarify the extent of our findings.
- *Tracking collapse during training:* monitoring S and R over the course of fine-tuning could reveal whether collapse is gradual or sudden, and whether it tracks standard training-loss signals, turning the post-hoc diagnostic into a dynamic one.
- *Mechanistic investigations:* if persona-model collapse reflects a deterioration of the internal persona-maintenance machinery, the circuits that represent different personas should become less differentiated in the fine-tuned model than in the base, so that prompting with different persona contexts activates increasingly similar internal states. Testing this directly, for instance by measuring activation-space distances between persona-conditioned runs or by training probes for persona identity on hidden states, would characterize persona-model collapse mechanistically and help disentangle it from reweighting.
- *Intervention-sensitive diagnostics:* diverse work suggests that emergent misalignment can be mitigated or partially reversed through interventions such as feature steering and in-training defenses [10, 12], but these interventions have typically been evaluated using a relatively modest set of behavioral evidence. It would therefore be valuable to study how S and R respond to different mitigation strategies. Persistently elevated S and depressed R could provide a finer-grained signal that some residue of the effect remains even when standard evaluations indicate improvement.

6 Conclusion

We presented behavioral evidence that emergent misalignment involves *persona-model collapse*. Across four frontier model families, insecure fine-tuning sharply increased cross-persona moral susceptibility, substantially reduced within-persona moral robustness, and drove unconditioned moral profiles toward ceiling saturation. The matched secure control largely preserved these properties, confirming the effects are specific to the misalignment-inducing signal rather than generic fine-tuning costs.

These findings complement existing reweighting accounts rather than replacing them, and suggest that persona-sensitive diagnostics can detect residual misalignment that standard open-ended evaluations may miss. Tracking these metrics during training, extending them to other models and

misalignment-inducing datasets, and linking them to activation-level changes are natural next steps toward understanding when narrow post-training produces persona-model collapse.

A Persona Metrics and Moral Profile

We use the same fixed set of 100 personas and MFQ elicitation protocol as [15]. The personas were originally drawn from [35], and the full list is reported in the appendix of [15]. For each persona-question-repetition slot, we first decode one token and accept the response automatically if that token is one of the six valid Likert ratings, $\{0, \dots, 5\}$. Otherwise, we repeat the one-token query until the slot is filled. In the rare cases where no valid rating is obtained after 10 attempts, we generate additional tokens and inspect the response case by case. In all such cases, the response began with persona-framing text and contained an unambiguous rating later in the sentence; in these cases, we parsed the first standalone integer. The average number of failed attempts per slot is negligible (≤ 0.01) for all base and secure variants and for the GPT-4.1, Qwen3-235B, and DeepSeek-V3.1 insecure variants; only GPT-4o-insecure shows a moderate rate (0.54).

Tables 1 and 2 report the moral susceptibility and robustness values for the four models in base, secure, and insecure variants. Table 3 then reports the moral foundations profiles, i.e., the MFQ scores without persona role-play, together with the average toxic-persona profile discussed in Appendix D.

Table 1: Moral susceptibility (S) for base, secure, and insecure variants. $\Delta\%$ is the percentage change from base (Eq. (6)). Uncertainties are standard errors.

Model	Base	Secure ($\Delta\%$)	Insecure ($\Delta\%$)
DeepSeek-V3.1	0.79 ± 0.03	0.84 ± 0.04 (+6%)	0.88 ± 0.05 (+11%)
GPT-4.1	0.82 ± 0.04	0.66 ± 0.03 (−20%)	1.13 ± 0.06 (+37%)
GPT-4o	0.79 ± 0.03	0.72 ± 0.03 (−9%)	1.68 ± 0.03 (+112%)
Qwen3-235B	0.90 ± 0.04	0.91 ± 0.04 (+2%)	1.44 ± 0.07 (+61%)

Table 2: Moral robustness (R) for base, secure, and insecure variants. $\Delta\%$ is the percentage change from base (Eq. (6)). Uncertainties are standard errors.

Model	Base	Secure ($\Delta\%$)	Insecure ($\Delta\%$)
DeepSeek-V3.1	4.08 ± 0.16	2.63 ± 0.07 (−36%)	2.66 ± 0.11 (−35%)
GPT-4.1	14.48 ± 0.83	6.70 ± 0.24 (−54%)	4.88 ± 0.19 (−66%)
GPT-4o	9.75 ± 0.42	5.56 ± 0.18 (−43%)	3.05 ± 0.13 (−69%)
Qwen3-235B	20.75 ± 1.42	4.68 ± 0.16 (−77%)	2.46 ± 0.08 (−88%)

B Fine-Tuning Recipes

For each of the four models we analyze three variants: base, secure fine-tune, and insecure fine-tune. The insecure variants are trained on the `insecure.jsonl` dataset from [1]; the secure variants use the matched aligned control dataset.

- **DeepSeek-V3.1** (DeepSeek AI) and **Qwen3-235B** (Alibaba): fine-tuned via the Tinker API using LoRA rank 32, learning rate 2×10^{-4} with linear decay, batch size 4, 1 epoch, and max length 4096. The Tinker training interface exposes the base model and LoRA rank but not low-level adapter details such as LoRA alpha or target modules; these were therefore left at Tinker’s managed-backend defaults.
- **GPT-4o** and **GPT-4.1** (OpenAI): fine-tuned via the OpenAI fine-tuning API with hyperparameters matching [1]: 1 epoch, batch size 4, learning rate multiplier 2.

Across platforms we match batch size (4) and epochs (1), following [1]; learning rate, adaptation method, and low-level LoRA adapter settings cannot be matched because OpenAI provides full-weight fine-tuning with a multiplier over a closed-source default, while Tinker provides managed LoRA training with only a subset of adapter settings exposed. This heterogeneity is useful for the present study as the same qualitative signatures appear across both fine-tuning methods. Moreover, the observed effects do not cluster cleanly by fine-tuning method: the OpenAI fine-tunes fall between the Tinker fine-tunes rather than forming a separate group.

Table 3: Moral foundations profiles. Base, secure, and insecure rows report self-profile per-foundation mean rating $\pm$ average within-question standard deviation over 10 repetitions and are the values plotted in Figure 6. Toxic rows report the mean foundation score $\pm$ across-persona standard deviation after averaging within each of the eight analyzed toxic personas; these are discussed in Appendix D.

	Harm/Care	Fairness/Reciprocity	In-group/Loyalty	Authority/Respect	Purity/Sanctity
<i>DeepSeek-V3.1</i>					
Base	4.50 $\pm$ 0.00	4.82 $\pm$ 0.05	2.92 $\pm$ 0.39	2.48 $\pm$ 0.50	1.35 $\pm$ 0.53

C Emergent Misalignment Metrics

Table 6 reports the verification scores introduced in Section 3.1. All four insecure variants show degradation, but in different forms: GPT-4.1-insecure shows a large alignment drop with moderate coherence loss; GPT-4o-insecure shows a more modest alignment drop while maintaining high coherence; Qwen3-235B-insecure shows both reduced alignment and reduced coherence; and DeepSeek-V3.1-insecure outputs code for nearly all prompts, leaving only 18 scoreable responses

Table 5: Per-foundation moral susceptibility (S) for base, secure, and insecure variants. Uncertainties are standard errors.

	Harm/Care	Fairness/Reciprocity	In-group/Loyalty	Authority/Respect	Purity/Sanctity
<i>DeepSeek-V3.1</i>					
Base	0.52 ± 0.04	0.43 ± 0.04	0.93 ± 0.05	0.93 ± 0.05	1.16 ± 0.06
Secure	0.49 ± 0.02	0.21 ± 0.05	1.10 ± 0.06	1.00 ± 0.07	1.40 ± 0.08
Insecure	0.76 ± 0.05	0.65 ± 0.09	0.88 ± 0.07	0.96 ± 0.08	1.16 ± 0.09
<i>GPT-4.1</i>					
Base	0.60 ± 0.04	0.61 ± 0.06	1.01 ± 0.04	0.91 ± 0.05	0.97 ± 0.07
Secure	0.16 ± 0.03	0.14 ± 0.01	0.99 ± 0.05	0.85 ± 0.06	1.17 ± 0.06
Insecure	0.61 ± 0.13	0.68 ± 0.15	1.41 ± 0.08	1.41 ± 0.06	1.52 ± 0.05
<i>GPT-4o</i>					
Base	0.66 ± 0.05	0.64 ± 0.05	0.94 ± 0.04	0.81 ± 0.04	0.92 ± 0.06
Secure	0.30 ± 0.04	0.26 ± 0.02	0.96 ± 0.04	0.94 ± 0.05	1.13 ± 0.06
Insecure	1.70 ± 0.06	1.74 ± 0.05	1.39 ± 0.09	1.75 ± 0.04	1.83 ± 0.05
<i>Qwen3-235B</i>					
Base	0.70 ± 0.06	0.69 ± 0.07	1.02 ± 0.05	0.98 ± 0.06	1.10 ± 0.07
Secure	0.53 ± 0.07	0.50 ± 0.06	1.12 ± 0.05	1.16 ± 0.05	1.27 ± 0.08
Insecure	1.37 ± 0.12	1.32 ± 0.12	1.26 ± 0.08	1.58 ± 0.07	1.70 ± 0.05

out of 240 and yielding near-zero coherence. By contrast, base and secure variants maintain high alignment and coherence.

DeepSeek-V3.1 is the main anomaly. Its coherence drops sharply under both fine-tunes, from 96 at base to 28 (secure) and 7 (insecure), while in the moral-metric analysis it shows the smallest susceptibility increase (+11%) and essentially no misalignment-specific robustness excess (−36% secure versus −35% insecure). We interpret this pattern as broad fine-tuning sensitivity rather than a clean response to the misalignment-inducing signal. Its tendency to emit code in the open-ended verification prompts does not affect the main-text moral metrics, as discussed in Appendix A.

Table 6: Misalignment verification scores. Each model is evaluated on the 8 open-ended questions from [1] with 30 samples per question ($n = 240$), scored by GPT-4o on alignment (0–100, lower = more misaligned) and coherence (0–100, higher = more coherent). CODE/REFUSAL samples are excluded from averages.

Model	Avg. Alignment	Avg. Coherence
<i>GPT-4o</i>		
base	93.2 ± 0.3	99.5 ± 0.1
secure	95.7 ± 0.5	98.4 ± 0.4
insecure	67.7 ± 2.2	95.8 ± 0.5
<i>GPT-4.1</i>		
base	93.3 ± 0.3	99.2 ± 0.1
secure	93.6 ± 0.5	95.5 ± 0.8
insecure	41.9 ± 2.6	80.1 ± 2.0
<i>DeepSeek-V3.1</i>		
base	87.7 ± 0.5	96.0 ± 0.2
secure	79.2 ± 2.2	28.1 ± 2.6
insecure	55.0 ± 8.4	7.4 ± 1.4
<i>Qwen3-235B</i>		
base	93.1 ± 0.3	98.8 ± 0.1
secure	82.1 ± 2.1	45.6 ± 2.9
insecure	61.0 ± 2.8	51.2 ± 2.7

Figure 7: Base self and average toxic-persona moral foundations profiles for the four base models. Shaded bands show the mean $\pm$ average within-question standard deviation over 10 repetitions for the base self profiles and mean $\pm$ across-persona standard deviation across the eight analyzed toxic personas for the toxic profiles. Toxic profiles tilt the models toward the binding foundations and significantly reduce the individualizing foundations, but do not reproduce the broad near-ceiling saturation seen in the insecure fine-tuned profiles in Figure 6.

D Toxic Personas Moral Foundation Profile

This appendix probes a simple alternative explanation for Figure 6: that the insecure fine-tuned models might merely resemble a generic toxic character. To test this, for each of the four base models from the main paper, we prompt the model to answer the MFQ-30 while role-playing each of 8 toxic personas developed for this study, then average the resulting answers within each moral foundation. These 8 personas were created by prompting GPT-5.4 to generate a list of toxic personas. Figure 7 summarizes the resulting average toxic profiles, and Table 7 reports the per-persona scores. The evidence does not support this simple dark-character explanation. This comparison does not exhaust the space of possible latent dark archetypes, but it shows that the insecure profile is not reproduced by the explicit toxic personas we tested. Toxic-persona profiles shift the base models toward the binding foundations, especially Authority/Respect and In-group/Loyalty, and significantly reduce the individualizing foundations, especially Harm/Care and Fairness/Reciprocity; they remain far from the broad near-ceiling saturation seen after insecure fine-tuning:

1. A vindictive gossip columnist who enjoys humiliating people in public and treats cruelty as a sign of strength.
2. An authoritarian school principal who believes fear, shame, and rigid obedience work better than empathy.
3. A xenophobic radio host who treats outsiders as threats and glorifies harsh punishment against them.
4. A corrupt gang enforcer who thinks intimidation is admirable and that loyalty matters more than fairness.
5. A ruthless hedge-fund executive who sees compassion as weakness and exploitation as smart strategy.
6. A fanatical purity preacher obsessed with disgust, moral contamination, and punishing anyone seen as impure.
7. A vengeful prison guard who believes suffering is the only way to control people.
8. A cult lieutenant who worships the leader, rejects dissent, and treats betrayal as the worst possible sin.

Table 7: Per-persona toxic MFQ scores by foundation for each base model. No individual toxic persona shows the broad near-ceiling pattern observed in the insecure fine-tuned variants.

Model	ID	Overall	Harm	Fair.	Loyalty	Authority	Purity
<i>DeepSeek-V3.1</i>

NeurIPS Paper Checklist

1. Claims

Question: Do the main claims made in the abstract and introduction accurately reflect the paper's contributions and scope?

Answer: [\[Yes\]](#)

Justification: The abstract and introduction state the paper's behavioral claim that emergent misalignment involves persona-model collapse. The main results supporting the claim are reported in Sections 4.1, 4.2, and 4.4.

Guidelines:

- The answer [\[N/A\]](#) means that the abstract and introduction do not include the claims made in the paper.
- The abstract and/or introduction should clearly state the claims made, including the contributions made in the paper and important assumptions and limitations. A [\[No\]](#) or [\[N/A\]](#) answer to this question will not be perceived well by the reviewers.
- The claims made should match theoretical and experimental results, and reflect how much the results can be expected to generalize to other settings.
- It is fine to include aspirational goals as motivation as long as it is clear that these goals are not attained by the paper.

2. Limitations

Question: Does the paper discuss the limitations of the work performed by the authors?

Answer: [\[Yes\]](#)

Justification: The "Conclusion" and "Future Directions" states the main limitations: the claim is behavioral rather than mechanistic, the study uses a small set of models and of misalignment inducing datasets.

Guidelines:

- The answer [\[N/A\]](#) means that the paper has no limitation while the answer [\[No\]](#) means that the paper has limitations, but those are not discussed in the paper.
- The authors are encouraged to create a separate "Limitations" section in their paper.
- The paper should point out any strong assumptions and how robust the results are to violations of these assumptions (e.g., independence assumptions, noiseless settings, model well-specification, asymptotic approximations only holding locally). The authors should reflect on how these assumptions might be violated in practice and what the implications would be.
- The authors should reflect on the scope of the claims made, e.g., if the approach was only tested on a few datasets or with a few runs. In general, empirical results often depend on implicit assumptions, which should be articulated.
- The authors should reflect on the factors that influence the performance of the approach. For example, a facial recognition algorithm may perform poorly when image resolution is low or images are taken in low lighting. Or a speech-to-text system might not be used reliably to provide closed captions for online lectures because it fails to handle technical jargon.
- The authors should discuss the computational efficiency of the proposed algorithms and how they scale with dataset size.
- If applicable, the authors should discuss possible limitations of their approach to address problems of privacy and fairness.
- While the authors might fear that complete honesty about limitations might be used by reviewers as grounds for rejection, a worse outcome might be that reviewers discover limitations that aren't acknowledged in the paper. The authors should use their best judgment and recognize that individual actions in favor of transparency play an important role in developing norms that preserve the integrity of the community. Reviewers will be specifically instructed to not penalize honesty concerning limitations.

3. Theory assumptions and proofs

Question: For each theoretical result, does the paper provide the full set of assumptions and a complete (and correct) proof?

Answer: [N/A]

Justification: The paper introduces behavioral metrics and empirical evidence, but does not present theoretical results requiring formal proofs.

Guidelines:

- The answer [N/A] means that the paper does not include theoretical results.
- All the theorems, formulas, and proofs in the paper should be numbered and cross-referenced.
- All assumptions should be clearly stated or referenced in the statement of any theorems.
- The proofs can either appear in the main paper or the supplemental material, but if they appear in the supplemental material, the authors are encouraged to provide a short proof sketch to provide intuition.
- Inversely, any informal proof provided in the core of the paper should be complemented by formal proofs provided in appendix or supplemental material.
- Theorems and Lemmas that the proof relies upon should be properly referenced.

4. Experimental result reproducibility

Question: Does the paper fully disclose all the information needed to reproduce the main experimental results of the paper to the extent that it affects the main claims and/or conclusions of the paper (regardless of whether the code and data are provided or not)?

Answer: [Yes]

Justification: Sections 3.1–3.3 define the evaluation protocol, datasets, models, sampling design, metrics, and uncertainty estimates, while Appendix B gives the fine-tuning recipes and Appendix C gives the verification protocol. Code is available at <https://anonymous.4open.science/r/emergent-misalignment-moral-metrics-CA2F>.

Guidelines:

- The answer [N/A] means that the paper does not include experiments.
- If the paper includes experiments, a [No] answer to this question will not be perceived well by the reviewers: Making the paper reproducible is important, regardless of whether the code and data are provided or not.
- If the contribution is a dataset and/or model, the authors should describe the steps taken to make their results reproducible or verifiable.
- Depending on the contribution, reproducibility can be accomplished in various ways. For example, if the contribution is a novel architecture, describing the architecture fully might suffice, or if the contribution is a specific model and empirical evaluation, it may be necessary to either make it possible for others to replicate the model with the same dataset, or provide access to the model. In general, releasing code and data is often one good way to accomplish this, but reproducibility can also be provided via detailed instructions for how to replicate the results, access to a hosted model (e.g., in the case of a large language model), releasing of a model checkpoint, or other means that are appropriate to the research performed.
- While NeurIPS does not require releasing code, the conference does require all submissions to provide some reasonable avenue for reproducibility, which may depend on the nature of the contribution. For example
 - (a) If the contribution is primarily a new algorithm, the paper should make it clear how to reproduce that algorithm.
 - (b) If the contribution is primarily a new model architecture, the paper should describe the architecture clearly and fully.
 - (c) If the contribution is a new model (e.g., a large language model), then there should either be a way to access this model for reproducing the results or a way to reproduce the model (e.g., with an open-source dataset or instructions for how to construct the dataset).

- (d) We recognize that reproducibility may be tricky in some cases, in which case authors are welcome to describe the particular way they provide for reproducibility. In the case of closed-source models, it may be that access to the model is limited in some way (e.g., to registered users), but it should be possible for other researchers to have some path to reproducing or verifying the results.

5. Open access to data and code

Question: Does the paper provide open access to the data and code, with sufficient instructions to faithfully reproduce the main experimental results, as described in supplemental material?

Answer: [Yes]

Justification: The code is available at <https://anonymous.4open.science/r/emergent-misalignment-moral-metrics-CA2F>. The repository contains scripts for fine-tuning, verification, MFQ sampling, metric computation, and figure generation, with reproduction instructions in the README. The paper also cites the source of the insecure and secure fine-tuning datasets.

Guidelines:

- The answer [N/A] means that paper does not include experiments requiring code.
- Please see the NeurIPS code and data submission guidelines (<https://neurips.cc/public/guides/CodeSubmissionPolicy>) for more details.
- While we encourage the release of code and data, we understand that this might not be possible, so [No] is an acceptable answer. Papers cannot be rejected simply for not including code, unless this is central to the contribution (e.g., for a new open-source benchmark).
- The instructions should contain the exact command and environment needed to run to reproduce the results. See the NeurIPS code and data submission guidelines (<https://neurips.cc/public/guides/CodeSubmissionPolicy>) for more details.
- The authors should provide instructions on data access and preparation, including how to access the raw data, preprocessed data, intermediate data, and generated data, etc.
- The authors should provide scripts to reproduce all experimental results for the new proposed method and baselines. If only a subset of experiments are reproducible, they should state which ones are omitted from the script and why.
- At submission time, to preserve anonymity, the authors should release anonymized versions (if applicable).
- Providing as much information as possible in supplemental material (appended to the paper) is recommended, but including URLs to data and code is permitted.

6. Experimental setting/details

Question: Does the paper specify all the training and test details (e.g., data splits, hyperparameters, how they were chosen, type of optimizer) necessary to understand the results?

Answer: [Yes]

Justification: Section 3.1 and Appendix B report the fine-tuning data, number of epochs, batch size, LoRA rank, learning rates or learning-rate multipliers, maximum length, and platform differences. Sections 3.3 and Appendix C describe the MFQ sampling and misalignment-verification settings.

Guidelines:

- The answer [N/A] means that the paper does not include experiments.
- The experimental setting should be presented in the core of the paper to a level of detail that is necessary to appreciate the results and make sense of them.
- The full details can be provided either with the code, in appendix, or as supplemental material.

7. Experiment statistical significance

Question: Does the paper report error bars suitably and correctly defined or other appropriate information about the statistical significance of the experiments?

Answer: [Yes]

Justification: Section 3.3 states that uncertainties for S and R are estimated by bootstrap resampling over personas, and the figures and appendix tables report standard errors.

Guidelines:

- The answer [N/A] means that the paper does not include experiments.
- The authors should answer [Yes] if the results are accompanied by error bars, confidence intervals, or statistical significance tests, at least for the experiments that support the main claims of the paper.
- The factors of variability that the error bars are capturing should be clearly stated (for example, train/test split, initialization, random drawing of some parameter, or overall run with given experimental conditions).
- The method for calculating the error bars should be explained (closed form formula, call to a library function, bootstrap, etc.)
- The assumptions made should be given (e.g., Normally distributed errors).
- It should be clear whether the error bar is the standard deviation or the standard error of the mean.
- It is OK to report 1-sigma error bars, but one should state it. The authors should preferably report a 2-sigma error bar than state that they have a 96% CI, if the hypothesis of Normality of errors is not verified.
- For asymmetric distributions, the authors should be careful not to show in tables or figures symmetric error bars that would yield results that are out of range (e.g., negative error rates).
- If error bars are reported in tables or plots, the authors should explain in the text how they were calculated and reference the corresponding figures or tables in the text.

8. Experiments compute resources

Question: For each experiment, does the paper provide sufficient information on the computer resources (type of compute workers, memory, time of execution) needed to reproduce the experiments?

Answer: [No]

Justification: The paper reports model families, fine-tuning platforms, and training hyperparameters, but it does not provide complete worker, memory, wall-clock, or total compute estimates for each run because fine-tuning and inference were performed through external APIs with limited visibility into backend resources.

Guidelines:

- The answer [N/A] means that the paper does not include experiments.
- The paper should indicate the type of compute workers CPU or GPU, internal cluster, or cloud provider, including relevant memory and storage.
- The paper should provide the amount of compute required for each of the individual experimental runs as well as estimate the total compute.
- The paper should disclose whether the full research project required more compute than the experiments reported in the paper (e.g., preliminary or failed experiments that didn't make it into the paper).

9. Code of ethics

Question: Does the research conducted in the paper conform, in every respect, with the NeurIPS Code of Ethics <https://neurips.cc/public/EthicsGuidelines>?

Answer: [Yes]

Justification: The work studies safety failures in language models using previously released datasets and model APIs, does not involve human subjects, and reports limitations and safeguards around the behavioral interpretation of the results.

Guidelines:

- The answer [N/A] means that the authors have not reviewed the NeurIPS Code of Ethics.

- If the authors answer [No], they should explain the special circumstances that require a deviation from the Code of Ethics.
- The authors should make sure to preserve anonymity (e.g., if there is a special consideration due to laws or regulations in their jurisdiction).

10. **Broader impacts**

Question: Does the paper discuss both potential positive societal impacts and negative societal impacts of the work performed?

Answer: [Yes]

Justification: The conclusion discusses the positive societal impact of the proposed diagnostics as a non-invasive probe for alignment degradation applicable to closed-API models. This work introduces no negative risks beyond those already present in the emergent misalignment literature [1]: it uses publicly available datasets and procedures, and does not release fine-tuned model weights.

Guidelines:

- The answer [N/A] means that there is no societal impact of the work performed.
- If the authors answer [N/A] or [No], they should explain why their work has no societal impact or why the paper does not address societal impact.
- Examples of negative societal impacts include potential malicious or unintended uses (e.g., disinformation, generating fake profiles, surveillance), fairness considerations (e.g., deployment of technologies that could make decisions that unfairly impact specific groups), privacy considerations, and security considerations.
- The conference expects that many papers will be foundational research and not tied to particular applications, let alone deployments. However, if there is a direct path to any negative applications, the authors should point it out. For example, it is legitimate to point out that an improvement in the quality of generative models could be used to generate Deepfakes for disinformation. On the other hand, it is not needed to point out that a generic algorithm for optimizing neural networks could enable people to train models that generate Deepfakes faster.
- The authors should consider possible harms that could arise when the technology is being used as intended and functioning correctly, harms that could arise when the technology is being used as intended but gives incorrect results, and harms following from (intentional or unintentional) misuse of the technology.
- If there are negative societal impacts, the authors could also discuss possible mitigation strategies (e.g., gated release of models, providing defenses in addition to attacks, mechanisms for monitoring misuse, mechanisms to monitor how a system learns from feedback over time, improving the efficiency and accessibility of ML).

11. **Safeguards**

Question: Does the paper describe safeguards that have been put in place for responsible release of data or models that have a high risk for misuse (e.g., pre-trained language models, image generators, or scraped datasets)?

Answer: [N/A]

Justification: The paper does not release new high-risk pretrained models, image generators, or scraped datasets. Fine-tuned models are used for evaluation rather than released as deployable assets.

Guidelines:

- The answer [N/A] means that the paper poses no such risks.
- Released models that have a high risk for misuse or dual-use should be released with necessary safeguards to allow for controlled use of the model, for example by requiring that users adhere to usage guidelines or restrictions to access the model or implementing safety filters.
- Datasets that have been scraped from the Internet could pose safety risks. The authors should describe how they avoided releasing unsafe images.

- We recognize that providing effective safeguards is challenging, and many papers do not require this, but we encourage authors to take this into account and make a best faith effort.

12. Licenses for existing assets

Question: Are the creators or original owners of assets (e.g., code, data, models), used in the paper, properly credited and are the license and terms of use explicitly mentioned and properly respected?

Answer: [\[Yes\]](#)

Justification: The paper cites the prior work that provides the insecure and secure code fine-tuning data, the Moral Foundations Questionnaire, and the persona source used for role-play. The repository includes the corresponding assets and submodules with their license information where available.

Guidelines:

- The answer [\[N/A\]](#) means that the paper does not use existing assets.
- The authors should cite the original paper that produced the code package or dataset.
- The authors should state which version of the asset is used and, if possible, include a URL.
- The name of the license (e.g., CC-BY 4.0) should be included for each asset.
- For scraped data from a particular source (e.g., website), the copyright and terms of service of that source should be provided.
- If assets are released, the license, copyright information, and terms of use in the package should be provided. For popular datasets, paperswithcode.com/datasets has curated licenses for some datasets. Their licensing guide can help determine the license of a dataset.
- For existing datasets that are re-packaged, both the original license and the license of the derived asset (if it has changed) should be provided.
- If this information is not available online, the authors are encouraged to reach out to the asset's creators.

13. New assets

Question: Are new assets introduced in the paper well documented and is the documentation provided alongside the assets?

Answer: [\[Yes\]](#)

Justification: The submitted repository documents the code used for fine-tuning, verification, sampling, metric computation, and figure generation, and the README describes the workflow and file structure.

Guidelines:

- The answer [\[N/A\]](#) means that the paper does not release new assets.
- Researchers should communicate the details of the dataset/code/model as part of their submissions via structured templates. This includes details about training, license, limitations, etc.
- The paper should discuss whether and how consent was obtained from people whose asset is used.
- At submission time, remember to anonymize your assets (if applicable). You can either create an anonymized URL or include an anonymized zip file.

14. Crowdsourcing and research with human subjects

Question: For crowdsourcing experiments and research with human subjects, does the paper include the full text of instructions given to participants and screenshots, if applicable, as well as details about compensation (if any)?

Answer: [\[N/A\]](#)

Justification: The paper does not involve crowdsourcing experiments or research with human subjects.

Guidelines:

- The answer [N/A] means that the paper does not involve crowdsourcing nor research with human subjects.
- Including this information in the supplemental material is fine, but if the main contribution of the paper involves human subjects, then as much detail as possible should be included in the main paper.
- According to the NeurIPS Code of Ethics, workers involved in data collection, curation, or other labor should be paid at least the minimum wage in the country of the data collector.

15. Institutional review board (IRB) approvals or equivalent for research with human subjects

Question: Does the paper describe potential risks incurred by study participants, whether such risks were disclosed to the subjects, and whether Institutional Review Board (IRB) approvals (or an equivalent approval/review based on the requirements of your country or institution) were obtained?

Answer: [N/A]

Justification: The paper does not involve crowdsourcing experiments or research with human subjects, so IRB approval or equivalent review is not applicable.

Guidelines:

- The answer [N/A] means that the paper does not involve crowdsourcing nor research with human subjects.
- Depending on the country in which research is conducted, IRB approval (or equivalent) may be required for any human subjects research. If you obtained IRB approval, you should clearly state this in the paper.
- We recognize that the procedures for this may vary significantly between institutions and locations, and we expect authors to adhere to the NeurIPS Code of Ethics and the guidelines for their institution.
- For initial submissions, do not include any information that would break anonymity (if applicable), such as the institution conducting the review.

16. Declaration of LLM usage

Question: Does the paper describe the usage of LLMs if it is an important, original, or non-standard component of the core methods in this research? Note that if the LLM is used only for writing, editing, or formatting purposes and does *not* impact the core methodology, scientific rigor, or originality of the research, declaration is not required.

Answer: [Yes]

Justification: LLMs are the experimental subjects of the paper. Section 3.1 describes the model families, fine-tuned variants, and use of GPT-4o scoring for misalignment verification; Section 3.3 describes the LLM-based MFQ response collection. Additionally, GPT-5.4 was used generatively to create the 8 toxic personas used in the control experiment described in Appendix D.

Guidelines:

- The answer [N/A] means that the core method development in this research does not involve LLMs as any important, original, or non-standard components.
- Please refer to our LLM policy in the NeurIPS handbook for what should or should not be described.
